^a All reactions were performed on a 0.10 mmol scale in a GC vial. ^b Yields determined by ¹H NMR spectroscopy using mesitylene as an internal standard; isolated yield in parenthesis. ^c 8 h.

2.2 General Procedure for the Reductive Rearrangement of Oximes: In a nitrogen-filled glovebox, a 2-mL GC vial or a dried 1-mL sealed tube equipped with a magnetic stir bar was charged with the desired amount of oxime, hydrosilane, toluene-*d*₈, and B(C₆F₅)₃. The GC vial or sealed tube was fitted with a cap and the reaction stirred at RT for 20 h in the glove box or 120 °C for 20 h in a preheated oil bath. After that, mesitylene (0.500 equiv) was added as an internal standard, and the yield was determined by ¹H NMR spectroscopy. The generated *N*-silylated products were rapidly converted into their N–H form upon exposure of the reaction mixture to air. Methyl *tert*-butyl ether (2 mL) was added to the residue, and the mixture was transferred to a 10-mL sample bottle by pipette. 1 M aqueous HCl solution (4 mL) was added, and the mixture was stirred at RT for 12 h. The organic layer was extracted with 4 × 10 mL of 1 M aqueous HCl solution. To the combined aqueous phases was added NaOH (10.0 g), and the mixture was stirred at RT for 4 h. The product was extracted into 4 × 15 mL of methyl *tert*-butyl ether. Removal of the solvent under reduced pressure yielded the crude amine. Further purification by flash column chromatography on silica gel with methyl *tert*-butyl ether : cyclohexane = 1 : 20 for arylamines or MeOH : *tert*-butyl ether = 1 : 10 for alkylamines as the eluent gave the corresponding amines.

6 Computational Data

All density functional theory (DFT) calculations were performed with the Gaussian 16 package.^[38] The 3D structures of the optimized species were generated using CYLview.^[39] Geometry optimization and vibrational frequency calculations of all stationary points were carried out at M06-2X^[40]/6-311G(d,p) level of theory. To get more accurate energies, single-point energies were computed at M06-2X/cc-PVTZ level for all the species along the reaction pathway. Solvent effects in toluene were treated with the polarizable continuum model (PCM) in both geometry optimization and single-point calculation.^[41]

Activation free energy barriers here are defined as the free energy difference between the transition state and the lowest-energy stationary point before it along the reaction pathway.

The formation of the primary amine **3a** pathway proceeding through the deoxygenation reaction of ion-pair **I6** or bissilyloxonium ion **I11** was also investigated. Through extensive scans for the hydride transfer from the borohydride to the nitrogen atom in **I6** or **I11**, it was found that there is no transition state to connect **I6** or **I11** with the related deoxygenation intermediates. Structures “**TS10**” and “**TS11**” (Figure S72) are *NOT* the transition states but structures obtained with a fixed N–H bond at 1.29 and 1.13 Å, respectively. The activation free energies of these two processes are estimated at more than 65 kcal/mol and 47 kcal/mol, respectively (Figures S64 and S68). The involvement of high-energy species in the formation of the primary amine **3a** can account for the high selectivity in favor of the secondary amine **2a** under the experimental conditions.
